Project 4 summary

Much of my first, second, and third report still applies to this current report in terms of software used to create this page with bootstrap and JavaScript. However, for clarity's sake I will restate those knowns in a condensed form as follows:

- HTML and CSS editor: Brackets
- SSH file uploader software: Cyberduck
- Tested on: Firefox, Google Chrome

The hardest part, right off the bat, for this project was wrapping my head around JavaScript (still). However, jQuery came easier than plain JavaScript; at least to me. It is quite an interesting language, with many uses.

I do need to apologize, however, as this project will be incomplete at the time of it's submission. It is possible to create entries in the list, but it is not possible to remove or edit them. It is fraught with bugs. However, I am out of time and am presenting what I do have.

I hope to improve this project in the coming week, but I would like to start and have the PHP project done and submitted before I return to this one. PHP is entirely new to me, so I want as much time with it as possible. I really do apologize, there is no excuse for the poor quality of this project.

On the up-side, I received a good bit of help with local storage from a previous student of yours. I could have copied his entire project and submitted that instead; but, in addition to that

being plagiarism and greatly against the rules of this institution, I wanted the experience of creating this project myself.

I will improve the quality of my next project in PHP, and I hope you will see that improvement both in the PHP project and in this one when I get around to improving it. Until, next time. Thank you very much for your time.
